

Redesign Rationale

1. Risk-based routing

In the as-is process, every request regardless of complexity went through the same full review chain, with no way to prioritize based on urgency or risk. To fix this, I introduced a risk classification step right after submission, categorizing each request as Low, Medium, or High risk. Low-risk requests are routed through a fast-track approval, while Medium/High-risk requests continue through the full review chain. This ensures reviewer time is spent where it matters most, and trivial changes no longer wait behind critical ones.

2. Duplicate/overlap check

The as-is process had no way to detect duplicate or conflicting requests across product lines and regions. To fix this, I added a duplicate/overlap check immediately after submission, which flags requests that overlap with existing active requests before they proceed further catching duplication or conflicts early, before both are separately approved.

3. Parallel CCB + Quality review

In the as-is process, CCB review and Quality sign-off happened sequentially, Quality couldn't begin until CCB finished, extending the total review time. To fix this, I redesigned the process so CCB and Quality review run in parallel for Medium/High-risk requests, cutting the total time these two stages take without reducing the scrutiny either one applies.

4. Status visibility

Although not shown as a separate step in the diagram, a real implementation of this redesign would also include automated status notifications sent to the requesting engineer at each major stage transition. This directly addresses the visibility gap identified in the pain-point analysis, engineers would always know where their request currently stands, rather than submitting a request and hearing nothing until a final decision.
